Current linear Flight Control Systems (FCS) algorithms are incapable of adapting to sudden changes in terms of aircraft configuration. It is well known that classical control approaches only provide a satisfying performance and robustness if the aircraft is close enough to the model assumed for control design.

A fault tolerant control scheme for actuator and sensor faults is proposed for a tilt-rotor unmanned aerial vehicle (UAV) system. The tilt-rotor UAV has a vertically take-off and landing (VTOL) capability like a helicopter during the take-off & landing while it could cruise with a high speed as a conventional

This example deals with fault-tolerant flight control of passenger jet undergoing outages in the elevator and aileron actuators. The flight control system must maintain stability and meet performance and comfort requirements in both nominal operation and degraded conditions where some actuators are no longer effective due to control surface impairment.

Fault-tolerant flight control systems are often complemented by a robust guidance system to achieve safe landing objective. For example, Menon et al. implemented a robust guidance algorithm for impaired aircraft based on a point mass nonlinear aircraft model. The guidance algorithm was formulated with the finite interval differential game.

A reconfigurable flight control system (FCS) is a flight control system that can accommodate the effects of faults by modifying the control system when faults occur during flight. The reconfigurable flight control system provides a significant enhancement to flight safety and performance in the event of a system fault.
