Positive feedback control of the op-amp is achieved by applying a small part of the output voltage signal at V_{out} back to the non-inverting (+) input terminal via

the feedback resistor, R_F . If the input voltage V_{in} is positive, the op-amp amplifies this positive signal and the output becomes more positive.

The following fact seems to be largely ignored: Feedback control is playing an

increasing rôle for computer systems. Philipp K. Janert intends to explain to computer scientists feedback control, and especially PID (proportional-integral-derivative) controllers, i.e. the far most popular industrial feedback loop.

If either the output or some part of the output is returned to the input side and utilized as part of the system input, then it is known as feedback. Feedback plays an important role in order to improve the performance of the control systems. In this chapter, let us discuss the types of feedback & effects of feedback.

Feedback loops Control systems can be open loop or closed loop. Open loop systems will just consider the input and then keep repeating the same task given the input, e.g. a microwave heats for a given time period without actually checking the temperature of the food.

What is feedback in a control system? - Quora

Electronic feedback loops are used to control the output of electronic devices, such as amplifiers. A feedback loop is created when all or some portion of the output is fed back to the input. A device

Feedback control systems must be designed to suit a predetermined purpose. Normally, only the controller can be appropriately designed, whereas the process and the sensor are predetermined or constrained. Feedback control systems can be designed to achieve specific behavior of the output variable, for example
